68 **Summary**

69

70 As SARS-CoV-2 becomes an endemic pathogen, detecting emerging variants early is critical for
71 public health interventions. Inferring lineage prevalence by clinical testing is infeasible at scale,
72 especially in areas with limited resources, participation, or testing/sequencing capacity, which
73 can also introduce biases. SARS-CoV-2 RNA concentration in wastewater successfully tracks
74 regional infection dynamics and provides less biased abundance estimates than clinical testing.
75 Tracking virus genomic sequences in wastewater would improve community prevalence
76 estimates and detect emerging variants. However, two factors limit wastewater-based genomic
77 surveillance: low-quality sequence data and inability to estimate relative lineage abundance in
78 mixed samples. Here, we resolve these critical issues to perform a high-resolution, 295-day
79 wastewater and clinical sequencing effort, in the controlled environment of a large university
80 campus and the broader context of the surrounding county. We develop and deploy improved
81 virus concentration protocols and deconvolution software that fully resolve multiple virus strains
82 from wastewater. We detect emerging variants of concern up to 14 days earlier in wastewater
83 samples, and identify multiple instances of virus spread not captured by clinical genomic
84 surveillance. Our study provides a scalable solution for wastewater genomic surveillance that
85 allows early detection of SARS-CoV-2 variants and identification of cryptic transmission.

86

87 **Introduction**

88

89 As SARS-CoV-2 transitions to endemicity, it continues to evolve, producing diverse new
90 lineages¹. Emerging variants of concern (VOCs) and variants of interest (VOIs) demonstrate
91 increased transmissibility, disease severity, and/or immune escape². Timely and accurate
92 quantification of local prevalence of SARS-CoV-2 variants is thus essential for effective public

93 health measures. However, existing strategies for variant detection based on virus genome
94 sequencing of biospecimens obtained from clinical testing (“clinical genomic surveillance”) are
95 expensive, inefficient, and have sampling bias because of systemic healthcare disparities,
96 particularly in poor and underserved communities^{3,4}.

97
98 In contrast, PCR-based wastewater surveillance of SARS-CoV-2 RNA is not subject to clinical
99 testing biases and can track temporal changes in overall SARS-CoV-2 prevalence in a region⁵⁻⁷,
100 but cannot identify epidemiological transmission links or monitor lineages in the population.
101 Virus genome sequencing from wastewater (“wastewater genomic surveillance”) has the
102 potential to cost-effectively capture community virus spread^{8,9}, acting as a surrogate to elucidate
103 lineage geospatial distributions and track emerging SARS-CoV-2 variants (including new
104 variants for which targeted assays do not yet exist), and provide genome sequence data needed
105 for transmission network analysis and interpretation¹⁰.

106
107 However, wastewater genomic surveillance is technically challenging⁹. Low viral loads, heavily
108 fragmented RNA, and PCR inhibitors in complex environmental samples lead to poor
109 sequencing coverage/quality¹¹. Additionally, tools for SARS-CoV-2 lineage classification, such
110 as pangolin¹² and UShER¹³, were designed for clinical samples containing a single dominant
111 variant, and cannot estimate relative abundances of multiple SARS-CoV-2 lineages in samples
112 with virus mixtures such as wastewater.

113
114 Here, we report a high-resolution approach to study community virus transmission using
115 wastewater genomic surveillance, leveraging several technical advances in wastewater virus
116 concentration and nucleic acid sequencing, and a computational tool for resolving multiple
117 SARS-CoV-2 lineages in short-read sequence data from a mixed sample (lineage deconvolution).
118 Because places of communal living, such as university campuses, are considered key sites for
119 virus spread and represent well-controlled and relatively isolated environments, they are ideal for
120 comparing the relative utility of clinical and wastewater genomic surveillance¹⁴. Accordingly, we
121 conducted a high-resolution, longitudinal wastewater genomic surveillance effort at the
122 University of California San Diego (UCSD) campus, in parallel with clinical genomic
123 surveillance from nasal swabs in the local community, from November 2020 to September 2021:
124 ten months that effectively capture the surges in the region caused by the three main VOCs,
125 Epsilon, Alpha and Delta¹.

126
127 Our wastewater genomic surveillance approach identified VOCs up to 2 weeks prior to detection
128 through clinical genomic surveillance, even though a large proportion of clinical SARS-CoV-2
129 samples are sequenced in San Diego relative to other cities in the United States. In addition to
130 providing a detailed history of community virus spread, wastewater genomic surveillance also
131 identified multiple instances of cryptic community transmission not observed through clinical
132 genomic surveillance. Matching wastewater and clinical genome sequences provided
133 epidemiological information identifying specific transmission events. Our results demonstrate
134 the viability of wastewater genomic surveillance at scale, enabling early detection and tracking
135 of virus lineages and guiding clinical genomic surveillance efforts.

136
137 **Results**

138

139 To directly compare wastewater genomic surveillance to clinical surveillance, we conducted a
140 large-scale SARS-CoV-2 genome sequencing study from wastewater samples collected daily
141 from 131 wastewater samplers covering 360 campus buildings, in many cases reaching single
142 building-level resolution. To identify epidemiological transmission links and monitor lineages in
143 the population, we sequenced all SARS-CoV-2 positive clinical and wastewater samples from
144 campus using a miniaturized tiled-amplicon sequencing approach. During this period of this
145 study, we collected and analyzed 21,383 wastewater samples: 19,944 wastewater samples from
146 the UCSD campus, and, for comparison, 1,439 wastewater samples from the greater San Diego
147 area, including the Point Loma wastewater treatment plant (the primary wastewater treatment
148 plant for the county with a catchment size of 2.3 million people) and 17 public schools spanning
149 four San Diego school districts¹⁵. We compared sequencing of 600 campus wastewater samples
150 to 759 genomes obtained from campus clinical swabs (46.2% of all positive tests on campus), all
151 processed by the CALM and EXCITE CLIA labs at UCSD. In addition, we compared 31,149
152 genomes obtained from clinical genomic surveillance of the greater San Diego community to
153 sequencing of 801 wastewater samples collected from San Diego county during the same period.
154

155

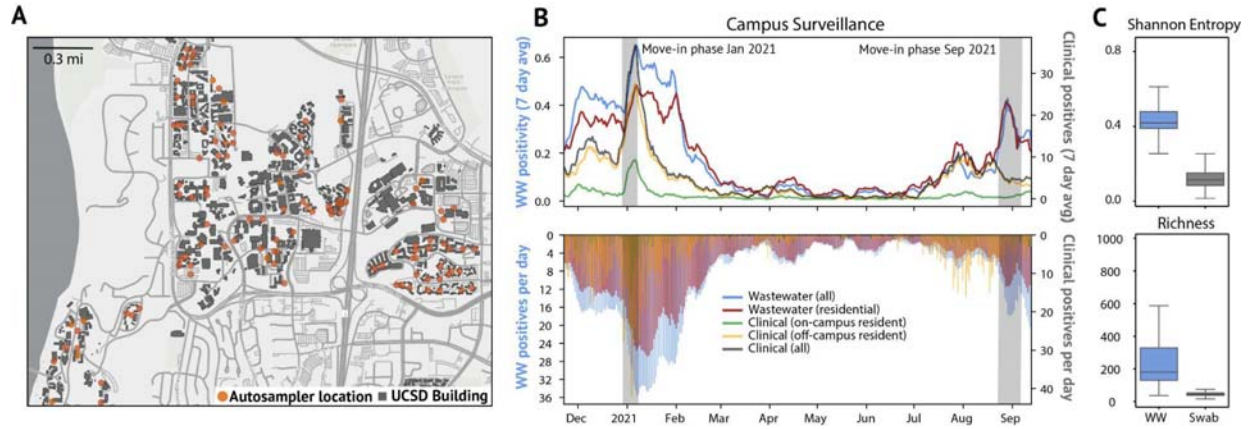

156 **High-resolution spatial sampling reveals micro-scale community spread**

157

158 We implemented a GIS (geographic information system)-enabled building-level wastewater
159 surveillance system to cover 360 buildings on the UCSD campus (**Figure 1A**). During the period
160 of daily wastewater sampling, approximately 10,000 students lived on campus and 25,000
161 individuals were on campus on a daily basis. We found that wastewater test positivity correlated
162 strongly with clinical test positivity at the same site (**Figure 1B**), showing that wastewater
163 effectively captures the community infection dynamics based on total viral load. This is also
164 consistent with our past studies that showed SARS-CoV-2 RNA can be detected ~85% of the
165 time downstream from buildings containing individuals known to be infected⁸.

166

167 Unlike qPCR-based mutant surveillance, genomic surveillance using full-length virus genomes
168 can detect which strains of SARS-CoV-2 are circulating in the population, and can identify
169 potential transmission links between infected individuals^{16,17}. To test the utility of wastewater
170 genomic surveillance for studying virus spread in the community, we obtained near complete
171 virus genomes for wastewater samples with cycle threshold (Ct) values as high as 38 (median
172 genome coverage: 96.49% [75.67% - 100.00%], **Extended Data Figure 1**). However, using two
173 common metrics of virus diversity, Shannon entropy (a measure of the uncertainty associated
174 with randomly sampling an allele) and richness (the number of single nucleotide variant, or
175 SNV, sites)¹⁸, we found that SARS-CoV-2 genetic diversity is significantly greater in wastewater
176 samples than clinical samples (**Figure 1C**, Mann-Whitney U test, $p < 0.001$ for each). This
177 suggests that multiple virus lineages, likely shed from different infected individuals, are often
178 present in wastewater samples.

179
180 **Figure 1: Campus sampling locations and SARS-CoV-2 testing statistics.** A. Geospatial
181 distribution of the 131 actively deployed wastewater autosamplers and the corresponding 360
182 university buildings on the campus sewer network. Building-specific data have been de-
183 identified in accordance with university reporting policies. B. Campus wastewater and diagnostic
184 testing statistics over the 295 day sampling period (WW = wastewater, positivity is the fraction
185 of WW samplers with a positive qPCR signal). C. Virus diversity in wastewater and clinical
186 samples: Boxplots of Shannon entropy (top) and richness (bottom) for each sample type.
187

188 **Sample deconvolution robustly recovers the abundance of SARS-CoV-2 lineages in mixed** 189 **samples**

190
191 Wastewater systems aggregate stool, urine, and other biological waste products carrying viruses
192 from multiple infected individuals in the community in a single location, allowing for sampling
193 of virus mixtures that are representative of local lineage prevalence. However, existing methods
194 for determining virus lineage from sequencing are intended for non-mixed clinical samples and
195 can only be used to identify a single (dominant) lineage per sample.
196

197 To fully capture the virus diversity in community biospecimens, we developed Freyja, a tool to
198 estimate the relative abundance of virus lineages in a mixed sample. Freyja uses a “barcode”
199 library of lineage-defining mutations to represent each SARS-CoV-2 lineage in the global
200 phylogeny¹⁹ (**Figure 2A**). To encode each sample, Freyja stores the SNV frequencies (proportion
201 of reads at a site that contain the SNV) for each of the lineage-defining mutations (**Figure 2B,**
202 **top**). Since SNV frequencies at positions with greater sequencing depth more accurately estimate
203 the true mutation frequency, Freyja recovers relative lineage abundance by solving a depth-
204 weighted least absolute deviation regression problem, a mixed sample analog of minimizing the
205 edit distance between sequences and a reference (**Figure 2B, bottom**). To ensure results are
206 meaningful, Freyja constrains the solution space such that each lineage abundance value is non-
207 negative, and overall lineage abundance sums to one.
208

209 To validate Freyja, we sequenced “spike-in” synthetic mixtures from five key SARS-CoV-2
210 lineages (Lineage A, Beta, Delta, Epsilon, and Gamma) at proportions ranging from 5% to 100%
211 in each sample, with between 1 and 5 different lineages per mixture (**Figure 2C**, and see **Table**
212 **1**). We found that Freyja robustly recovered the expected lineage abundances for all mixtures,
213 even for lineages at 5% abundance (**Figure 2D**, and see **Extended Data Figure 2** for lineage
214 specific predictions). To further validate Freyja, we used wastewater samples from the UCSD

215 isolation dorns as well as Point Loma wastewater treatment plant, collection sites likely to
 216 contain mixed-lineage samples, to compare Freyja-detected lineages with qPCR testing for 8
 217 mutations associated with different variants of concern (N501Y, DelHV69/70, DelY144, K417N,
 218 K417T, E484Q, P681R and L452R, **Figure 2E**). We found that Freyja consistently identified the
 219 same lineages as qPCR testing, but, as expected, also identified additional lineages with SNVs
 220 not included in our qPCR panel that were known to be circulating in San Diego at the time of
 221 collection. Combined, these results show that Freyja robustly estimates viral lineage abundance
 222 from samples containing a mixture of lineages, including synthetic virus mixtures and field
 223 wastewater collections.
 224

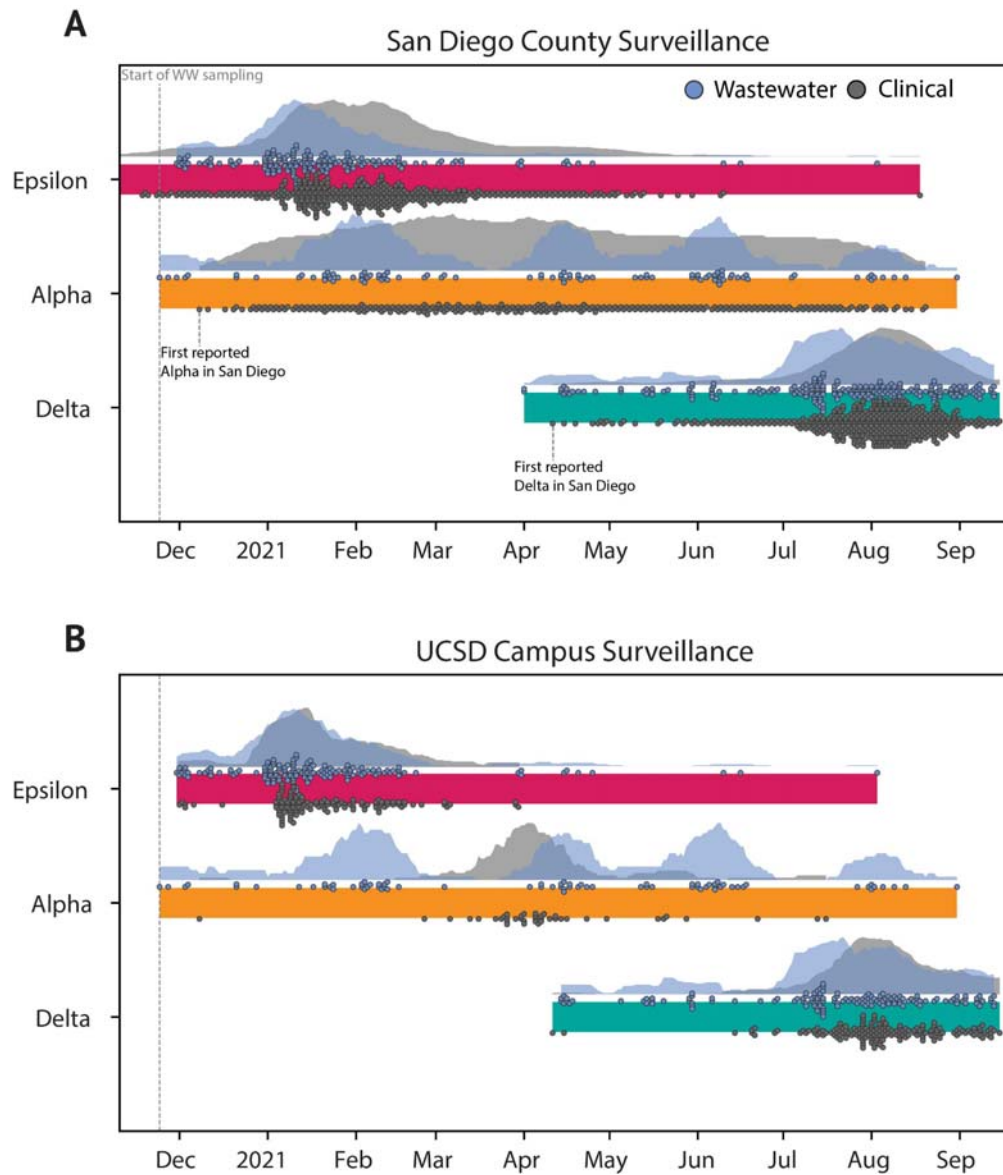

225
 226
 227 **Figure 2: Sample deconvolution robustly recovers relative virus abundance.** A. Subset of
 228 lineage defining mutation “barcode” matrix. Each row represents one lineage (out of >1000
 229 lineages included in the USHER global phylogenetic tree), and individual nucleotide mutations
 230 are represented as columns. B. Single nucleotide variant frequencies obtained from iVar used for
 231 recovering relative abundance of each lineage. C. Schematic of the spike-in validation
 232 experiment. D. Depth-weighted de-mixing estimates of the virus abundance versus
 233 expected/known abundance. Details on lineage specific predictions are provided in
 234 **Supplemental Figure 2**. E. Comparison of wastewater sample deconvolution with VOC qPCR
 235 panel, with lookup table (bottom) showing amino acid mutations corresponding to each variant.
 236

237 Detection of early and cryptic community transmission in wastewater

238
 239 SARS-CoV-2 RNA concentrations in wastewater have been shown to be an early indicator of
 240 rising COVID-19 community incidence^{8,20} (and see **Extended Data Figure 3A**), but whether

241 wastewater can be used to detect emerging variants, including VOCs and VOIs, prior to their
242 observation in clinical surveillance is unknown. To test if wastewater can enable early detection
243 of emerging lineages, we applied Freyja to our wastewater sequencing data and compared the
244 collection date of VOC positive samples from wastewater with the collection dates of samples
245 from clinical genomic surveillance (**Figure 3A**). With only 2.6% as many sequenced wastewater
246 samples as sequenced clinical samples, we detected the Alpha and Delta VOC lineages in
247 wastewater genomic surveillance up to 14 days prior to their first detection in genomic clinical
248 surveillance (Epsilon was circulating at the start of wastewater collection, and thus could not be
249 detected early). Since emerging VOC lineages may evade immune responses or lessen the
250 effectiveness of public health interventions¹⁶, this early detection provides additional time to
251 make necessary adjustments to existing countermeasures.

252
253 To test if wastewater genomic surveillance can identify changes in the abundance of circulating
254 lineages, we compared VOC detection rates in clinical and wastewater sequencing over time. We
255 found that both wastewater and clinical genomic surveillance tracked changes in lineage
256 abundance, but increases in lineage detection frequency were generally observed first in
257 wastewater surveillance. For example, for the Epsilon variant, which was first detected in San
258 Diego in September of 2020, we observed increases in detection frequency in wastewater
259 approximately 5 days prior to the corresponding increase in clinical genomic surveillance data
260 (**Figure 3A**, see **Methods**). To study the effectiveness of wastewater genomic surveillance at a
261 smaller community scale, we restricted our analysis to samples from the UCSD campus. We
262 found that wastewater genomic surveillance consistently identified the three major VOCs
263 (Epsilon, Alpha, and Delta) throughout their period of occurrence, despite detection gaps of one
264 month or longer in clinical surveillance that included regular asymptomatic testing (**Figure 3B**).
265 From mid-December to late-March, the Alpha variant was detected more than once per week on
266 average in wastewater but was not detected by clinical surveillance. Similarly, wastewater
267 surveillance detected continued Delta transmission from mid-April to mid-June, but no cases
268 were identified by clinical surveillance.

269
270

271 **Figure 3: Freyja recovers early and cryptic transmission of SARS-CoV-2 variants of**
272 **concern** A. Timeline and normalized epidemiological curves for VOC detection in both
273 wastewater and clinical sequences from San Diego County for the 3 major VOCs in circulation
274 during the sampling period. Both Alpha and Delta are detected first in wastewater before clinical
275 samples. Markers for clinical detections correspond to the ceiling of the detection count divided
276 by 30, while wastewater markers correspond to a single detection. B. Timeline and
277 epidemiological curves for VOC detection in the campus samples. Markers correspond to a
278 single detection event for both clinical and wastewater surveillance. All wastewater detections
279 correspond to an estimated VOC prevalence of at least 10%.

280

281 To study the effectiveness of wastewater surveillance in detecting and tracking other emerging
282 variants, we aggregated all wastewater sequencing data to estimate the temporal profile of
283 community lineage prevalence. We found that estimates of lineage abundance using wastewater
284 enable early identification of other VOCs/VOIs, even for lineages that are rarely observed in

285 clinical surveillance (**Figure 4**). For example, we detected the Mu (B.1.621) variant via
286 wastewater genomic surveillance on July 27th, nearly four weeks prior to its first detection
287 through clinical genomic surveillance on campus, on August 23rd (**Figure 4A,C**). However,
288 despite persistent Mu detection in campus wastewater throughout July and early August, we did
289 not detect the Mu variant in clinical or wastewater genomic surveillance on campus in
290 September, suggesting that local community transmission did not continue. In more recent data,
291 we identified the Omicron variant (B.1.1.529 and descendants) at an abundance of near 1% on
292 November 27th, more than 1 week prior to the first clinical detection in San Diego on December
293 8th (**Extended Data Table 2**). To confirm these findings, we applied our VOC qPCR panel to
294 the same samples and consistently detected two mutations associated with the Omicron variant
295 (DelHV69/70 and N501Y) in samples detected after November 27th, while neither was detected
296 in samples from earlier in November.

297
298 To test if Freyja continues to provide representative estimates of lineage prevalence for mixtures
299 containing closely related lineages, we analyzed the rise of the Delta variant (B.1.617.2) and its
300 sublineages (AY.*) in San Diego, from June-September 2021 (**Extended Data Figure 3B,C**). At
301 both the UCSD campus and the Point Loma wastewater treatment plant, we identified the rapid
302 emergence of B.1.617.2 and its sublineages (AY.*), along with low but persistent levels of the
303 P.1 (Gamma) variant. The relative abundances of each of the variants were within 2-fold of
304 prevalence estimates observed in clinical nasal swab data, suggesting that Freyja effectively
305 identifies prevalence even for closely related lineages, both at the university and county-scale.
306

307
308 **Figure 4: Deconvolution recovers a fine-grained estimate of virus population dynamics.** A.
309 Prevalence of SARS-CoV-2 variants in UCSD clinical surveillance, and B. Variant prevalence in
310 all clinical samples collected in San Diego County. C, D. Variant prevalence in wastewater at
311 UCSD as well as the greater San Diego County (includes wastewater samples collected from
312 Point Loma wastewater treatment plant as well as public schools in the San Diego districts).
313 Further analysis of Point Loma wastewater samples is shown in **Extended Data Figure 3**. All
314 curves show rolling average, window ± 10 days. “Other” contains all lineages not designated as
315 VOCs. Bottom panels show number of sequenced samples per day.

316 317 **Wastewater identifies both known and unknown history of campus infections**

318
319 Phylogenetic analysis of virus genomes can be used to identify fine-scale spatial and temporal
320 transmission networks, but it is unknown if wastewater can be used to further refine possible
321 sites of transmission, elucidate transmission networks (“who-infected-whom”), or identify
322 specific infected individuals¹⁷. To investigate the scale, structure, and timing of SARS-CoV-2
323 spread on campus, we reconstructed a maximum likelihood phylogenetic tree for each of the
324 major VOCs using all high-quality genomes (see **Methods** for details) obtained from the UCSD

325 campus, as well as reference sequences for each lineage obtained elsewhere in the United States
326 (**Figure 5A-C**). In each tree, we identified many independent introductions, some of which led to
327 extended transmission on campus. The resulting virus diversity among the VOCs present on
328 campus enables ruling out of most transmission links and suggests campus virus spread consisted
329 of many separate, small outbreaks.

330
331 To analyze the spatial structure of virus spread, we identified collection sites for wastewater
332 sequences connected to transmission chains on campus, with building-specific resolution
333 (**Figure 5 A-C**, *building specific transmission data available upon request*). We observed
334 multiple small, linked outbreaks clustered in nearby buildings. Campus isolation protocol
335 required students in congregate living to relocate to an isolation dorm and linkages in the
336 isolation dorm wastewater samples reflected this co-location. We also found multiple instances
337 of successive exactly matching sequences from wastewater collected from a single building,
338 suggesting continued viral shedding from the same infected individuals, possibly due to extended
339 shedding in stool^{21,22}.

340
341 To study the temporal delay between clinical and wastewater lineage detection, we compared
342 collection times of sequences from campus wastewater that match sequences from campus
343 clinical surveillance (including non-VOC lineages). We found 20 exact sequence matches and
344 103 near-matches (SNP distance of 3 or less) but did not observe any overall bias towards earlier
345 or later detection in wastewater (**Figure 5D**), suggesting that on average, wastewater and clinical
346 genomic surveillance identify a similar timing of individual detection events. However, in cases
347 of delayed or missed detection by clinical surveillance, detections occur first in wastewater,
348 further suggesting that wastewater genomic surveillance can reveal the presence of specific
349 genome sequences prior to clinical surveillance.

Figure 5: Wastewater identifies clinically known and unknown virus transmission. A-C. Maximum likelihood phylogenetic trees for each of the dominant variants of concern using high quality samples obtained at UCSD, as well as a representative set of sequences from the entire United States. Wastewater sequences from the same sampler that differ by 1 or fewer SNPs are denoted with a red asterisk. Location information is provided for select outbreaks. D. Pairwise comparison of collection date for matching and near-matching wastewater and nasal swab samples obtained at UCSD. Positive values indicate earlier collection in nasal swabs, and negative values indicate earlier detection in wastewater.

361

362 **Discussion**

363

364 We show that improved virus concentration from wastewater, coupled with a method for
365 resolving multiple lineages from mixed samples, captures community virus lineage prevalence
366 and enables early detection of emerging variants, often before observation in clinical
367 surveillance. By sequencing both clinical and wastewater samples from the UCSD campus, we
368 detect VOCs persistently in wastewater even when their appearance in clinical samples is
369 intermittent. However, we also found occasions when rarer lineages, like B.1.1.318, were
370 detected in clinical samples but not in wastewater. This is not unexpected on campus since many
371 students living off-campus did not contribute to campus wastewater but were still clinically
372 tested as part of testing mandates and policies. In the larger San Diego community context, this
373 suggests that we may not be able to identify lineages circulating at low prevalence using a single
374 wastewater collection site. In addition, we note that clinical sequences identified from the
375 community may not be observable in the contributing catchment, as precise geolocation of all
376 clinical samples was not possible. On the other hand, we also observed rare lineages in
377 wastewater not seen in clinical samples from campus or the community. Since campus testing
378 mandates are unable to capture all cases (e.g. fully vaccinated individuals were not required to
379 test and not all community samples were sequenced), rare lineages can be missed.

380

381 The considerable benefits of wastewater surveillance may stem from biases in clinical testing,
382 including population testing availability and compliance, university quarantine policies, and
383 asymptomatic transmission, which may distort estimates of virus lineage prevalence from
384 clinical samples. Wastewater offers less biased and more consistent viral lineage prevalence
385 estimates, especially in areas with limited access and/or higher testing hesitancy rates. Since it
386 requires considerably fewer samples, it is also more cost-effective than clinical testing, and could
387 serve as a long-term passive surveillance tool. This is particularly important for developing
388 public health interventions in low-resource and underserved communities, where widespread
389 clinical genomic surveillance for SARS-CoV-2 remains limited.

390

391 Wastewater is an information-dense resource for estimating the prevalence of specific viral
392 lineages, providing a community wide-snapshot not only of overall infection dynamics but of the
393 rise and fall of specific VOCs. Our method, Freyja, deconvolutes these information-rich mixtures
394 of virus lineages. For a large catchment area, such as San Diego's Point Loma wastewater
395 treatment plant, which covers over 2 million residents, even limited sampling may accurately
396 estimate lineage prevalence in the population and provide an early warning indicator of the rise
397 of new VOCs. In addition, wastewater genomic surveillance with building-level resolution
398 provides a detailed description of the structure and dynamics of community virus transmission,
399 and can be used to better direct public health interventions.

400

401 As SARS-CoV-2 continues to evolve, the risk of new VOCs remains high and there is a growing
402 need to identify these viruses ahead of their proliferation in the community. Accordingly,
403 development of technologies that are cost-effective, reduce biases, and provide leading rather
404 than trailing indicators of infection are essential to removing "blind spots" in our understanding
405 of local virus dynamics. Although technical issues have made wastewater sequencing difficult to
406 perform at scale, our key advances in virus concentration and sample deconvolution provide

407 evidence that this approach is now viable. Continued improvements to sequencing turnaround
408 speeds, lineage barcoding, and haplotype recovery from mixed samples will further accelerate
409 efforts to achieve earlier identification of emerging variants and improve the precision and
410 effectiveness of interventions.

411

412 **Methods**

413

414 **Wastewater sampling**

415

416 *High-resolution spatial sampling at the campus level*

417 131 wastewater autosamplers collecting 24h time-weighted composites were deployed across
418 manholes or sewer cleanouts of 360 campus buildings. GIS (geographic information systems)
419 informed analyses as well as agent-based network modeling of SARS-CoV-2 transmission on the
420 UCSD campus enabled identification of most optimal locations for wastewater sampling. During
421 the pilot phase (November 23-Dec 29th 2020), 68 samplers were prioritized to cover 239
422 residential buildings identified as the highest risk areas for large outbreaks on campus as a part of
423 an observational study of wastewater monitoring in high-density buildings²³. This was based on
424 preliminary dynamic modeling which showed the largest potential outbreaks to occur within the
425 largest residential buildings⁸. In addition to the observational study of wastewater monitoring in
426 these high-density buildings, a cluster randomized study was also performed concurrently. This
427 included a randomized modified version of a stepped wedge crossover design, in which there
428 was random assignment of manholes for wastewater sampling. Clusters of manholes associated
429 with residential buildings were randomized to receive wastewater monitors at one of two-time
430 steps to evaluate the impact of wastewater monitoring on outbreak size in the associated
431 buildings. During the same time period, all students in these residences were mandated to
432 undergo weekly diagnostic testing which was used to validate the utility of building-level
433 wastewater monitoring. Furthermore, on-campus residences were initially focused due to the
434 relatively static nature of the population which enabled a more robust cross-validation of the
435 sensitivity and efficacy of the wastewater surveillance. The coverage of wastewater surveillance
436 was then increased to cover the rest of the campus buildings (including non-residential buildings
437 on campus) from January 2021. Four of the deployed wastewater samplers covered the
438 designated isolation and quarantine buildings on campus.

439 Wastewater composites were collected from the 131 samplers every day for the on-campus
440 residence buildings and Monday through Friday for the nonresidential campus buildings. 19,944
441 wastewater samples were collected and analyzed for the presence of SARS-CoV-2 RNA via RT-
442 qPCR between November 23rd 2020 and September 20th 2021. During this time, 9700 students
443 lived in campus residences and 25,000 worked on campus on a daily basis. Between October
444 2020 to January 1st 2021, all on-campus residents were mandated to test on a bi-weekly basis
445 and on a weekly basis from January 2nd 2021 (start of the Winter term). However, fully
446 vaccinated individuals were not mandated to test on a regular basis. Automated, localized
447 wastewater-triggered notifications were sent to the residents/employees of buildings associated
448 with a positive wastewater signal which further led to a surge in testing uptake rates by 2 to 40-
449 fold in the associated buildings.

450

451 *Wastewater sampling at the county level*

452 24h flow-weighted composites were collected thrice a week from the main pump station for the
453 Point Loma wastewater treatment plant, the primary treatment plant serving the greater San
454 Diego county with a catchment size of approximately 2.3 million. 96 wastewater samples were
455 collected between February 24th 2021 to October 20th 2021.

456

457 **Wastewater sample processing and viral genome sequencing**

458

459 *Sample processing*

460 SARS-CoV-2 RNA was concentrated from 10ml of raw sewage and processed as described
461 elsewhere⁶. In brief, the viral RNA was concentrated using an automated affinity capture
462 magnetic hydrogel particle (Ceres Nanosciences Inc., USA) based concentration method after
463 which the nucleic acid was extracted and sample eluted in 50uL of elution buffer. The extracted
464 RNA was then screened for SARS-CoV-2 RNA via RT-qPCR for 3 gene targets (N1, N2 and E-
465 gene). PMMoV (pepper mild mottle virus) was also screened to adjust for changes in load. To
466 cross-validate the ability of the deconvolution tool in reliably resolving mixtures of strains in
467 wastewater, the wastewater samples from the county as well as the ones from the isolation dorms
468 on campus (where multiple infected individuals were isolating) were also run through a PCR
469 panel targeting 8 mutations associated with the strains designated as VOCs. The mutations
470 screened for in wastewater using RT-qPCR included N501Y, DelHV69/70, DelY144, K417N,
471 K417T, E484Q, P681R and L452R (Promega Corp. Cat# CS3174B02).

472

473 *Miniaturized wastewater SARS-CoV-2 amplicon sequencing*

474 The Swift Normalase® Amplicon Panels (SNAP) kit (PN: SN-5X296 (core) COVG1V2-96
475 (amplicon primers), Integrated DNA Technologies, Coralville, IA) was used on RNA from
476 wastewater samples that were positive for SARS-CoV-2 RNA to prepare the multiplex NGS
477 amplicon libraries and indexed using the SN91384 series of dual indexing oligos, yielding up to
478 1536 index pairs per pool. A miniaturized version of the protocol was used with the following
479 modifications: the Superscript IV VILO (Thermo Fisher, Carlsbad, CA) cDNA synthesis
480 reaction was scaled down to ~1/12 the normal reaction volume with 0.333uL of enzyme mix and
481 1.333uL of RNA being used. The multiplex amplicon amplification and Ampure XP bead
482 purification steps were scaled down ~1/6 the normal reaction volume. The Index adapter PCR
483 reaction and Ampure XP bead purification steps were scaled down to ~2/13 the normal reaction
484 volume. The final library resuspension volume was 29uL. 1uL of each library was pooled for an
485 initial shallow NGS run on a MiSeq (Illumina, San Diego, CA) using a Nano flow cell. This
486 equal volume pool was used to estimate the differential volumes required for similar read depths
487 across samples using a NovaSeq SP or S4 flow cell (Illumina, San Diego, CA). Between 5uL and
488 0.2uL of library material, depending on the data provided from the MiSeq Nano run, was
489 pipetted into a single pool for the NovaSeq run. Transfer volumes were capped at 5uL to reduce
490 pipetting time and because these types of “high volume” samples typically contained a higher
491 proportion of likely adapter dimers that inhibit flow cell performance for all samples. A
492 Dragonfly Discovery (SPT Labtech, UK) was used to dispense reaction master mixes or water
493 depending on the step. A BlueWasher (BlueCatBio, MA) was used for high throughput
494 centrifugal 384-well plate washing during the AmpureXP bead reaction cleanup steps. An IKA
495 MS3 Control linear plate mixer (IKA Works Inc, Wilmington, NC) set to 2600 RPM for 5’ was
496 used to resuspend the AmpureXP beads during the rehydration steps. A Mosquito Genomics HV
497 16 channel robotic liquid handler (SPT Labtech, UK) was used to dispense the RNA, the reaction

498 master mixes, and prepare the equal volume pools for the initial MiSeq Nano (Illumina, San
499 Diego, CA) balancing runs. A Mosquito X1 single channel “hit picker” robotic liquid handler
500 (SPT Labtech, UK) was used for the final library balancing for the NovaSeq (Illumina, San
501 Diego, CA) NGS lanes.

502

503 Sequencing data were analyzed using the C-VIEW (COVID-19 Viral Epidemiology Workflow)
504 platform for initial QC and SARS-CoV-2 lineage assignment and phylogenetics. In brief,
505 sequencing reads are aligned with minimap2²⁴, and primer sequences trimming and quality
506 filtering is applied using the iVar trim method¹⁸. Sequencing depth and single nucleotide variant
507 (SNV) calls are obtained using samtools mpileup²⁵ and the iVar variants method¹⁸.

508

509 **Virus diversity**

510

511 As reported previously¹⁸, virus SNVs were used to characterize the populations derived from
512 wastewater and clinical samples. Richness was defined as the total number of SNV sites, and
513 mean Shannon entropy was defined as

514

$$H(\mathbf{p}) = \frac{1}{N} \sum_{i=1}^N -p_i \log_2(p_i) - (1 - p_i) \log_2(1 - p_i).$$

515

516

517 **Wastewater sample deconvolution**

518

519 To infer relative abundance within a wastewater sample, we use a “barcode” matrix containing
520 the lineage defining mutations for each known virus lineage,

521

$$A = \begin{bmatrix} \mathbf{a}_{1,1} & \dots & \mathbf{a}_{1,N} \\ \vdots & \ddots & \vdots \\ \mathbf{a}_{M,1} & \dots & \mathbf{a}_{M,N} \end{bmatrix}$$

522

523

524 where $\mathbf{a}_{i,j}$ denotes the i -th lineage, at mutation j . Lineage defining mutations are obtained from
525 the USHER global phylogenetic tree using the matUtils package¹³. Similarly, we let \mathbf{b} and \mathbf{d}
526 encode the frequency of each mutation and the corresponding sequencing depth (using the log-
527 transform $\mathbf{d}_i = \log_2(\text{depth}_i + 1)$ to adjust for large differences in depth across amplicons),

528

$$\mathbf{b} = \begin{bmatrix} b_1 \\ \vdots \\ b_N \end{bmatrix}, \mathbf{d} = \begin{bmatrix} d_1 \\ \vdots \\ d_N \end{bmatrix}.$$

529

530

531 We can then write this as a constrained (weighted) least absolute deviations problem

$$\hat{\mathbf{x}} = \underset{\mathbf{x} \geq 0}{\operatorname{argmin}} \sum_{i=1}^N \|A^T \mathbf{x} - \mathbf{b}\|_{1W}, \quad \text{where} \quad \|\mu\|_{1W} = \sum_{i=1}^N d_i |\mu_i|$$

532

533 which yields the “demixing” vector $\hat{\mathbf{x}} = [\hat{x}_1 \dots \hat{x}_M]$ that specifies the relative abundances of
534 each of the known haplotypes. Analysis was only performed on samples with greater than 70%
535 coverage, with the exception of March samples from UCSD for which all samples with greater

536 than 50% coverage were used. Constrained minimization is performed in Python using the cvxpy
537 convex optimization package^{26,27}. Mapping of lineages to variant WHO lineages (VOCs, VUMs,
538 etc.) is performed using curated lineage data from outbreak.info¹.

539

540 **Spike-in mixture experiment**

541

542 RNA was isolated from supernatants of a mammalian cell culture infected with one of five
543 strains of SARS-CoV-2. (A, B.1.1.7, B.1.351, P.1, or B.1.617.2).

544

545 *RNA concentration standardization*

546 Virus concentration was quantified by the UCSD EXCITE COVID testing laboratory using the
547 Thermo COVID-19 Test kit (PN:A47814, Thermo Scientific Corporation, Carlsbad, CA). The
548 median Cq values (N-gene, Orf1ab, & S-gene (where applicable)) was calculated and used to
549 determine how much the RNA needed to be diluted with water to reach a Cq value of 23. A post
550 dilution RT-qPCR reaction was performed and used to calculate the final dilution of the more
551 concentrated samples to the new target value of Cq 23.296. The number of freeze thaw cycles
552 between RNA samples was kept the same.

553

554 *Virus Mixing*

555 RNA standardized in the prior section was used to make a volumetric mixing array (final volume
556 10uL) using a Mosquito X1 HV robotic liquid handler (SPT Labtech, UK). Pairwise mixes of
557 5:95, 10:90, 20:80, 60:40, and 50:50 were made for each virus strain and in both directions.
558 Equal mixes (20%) for each of the five test strains were made. 25% mixes and 33% mixes were
559 made for a subset of possible combinations and controls of 100:0 were prepared. See Table 1 for
560 complete array.

561

562 **Estimation of delay in detection frequency**

563

564 Estimation of the lag time between epidemiological curves for wastewater and clinical
565 surveillance of the Epsilon variant in San Diego was performed by identifying the shift with
566 maximal cross-correlation. All time points leading up to the time of initial peak in detection
567 frequency were included for both wastewater and clinical data.

568

569 **Phylogenetic analyses**

570

571 Reconstruction of maximum likelihood trees was performed on all SARS-CoV-2 VOC genomes
572 with 10x genome coverage >95% and quality score >20 obtained from UCSD campus sampling,
573 using IQtree²⁸. This analysis included 150 (112 clinical, 38 wastewater) Epsilon, 49 (37 clinical,
574 12 wastewater) Alpha, and 160 (136 clinical, 24 wastewater) Delta lineage genomes from
575 UCSD, in addition to 60 Epsilon, 20 Alpha, and 39 Delta randomly selected genomes from
576 elsewhere in the United States. We also masked known homoplastic sites prior to tree
577 reconstruction²⁹. Analysis of temporal comparison was performed on 608 samples (443 clinical,
578 165 wastewater, all lineages were included) with 10x genome coverage >95% and quality score
579 >20 from UCSD. Sample collection SNP distances were calculated without considering
580 ambiguous bases and gaps.

581

582 **Code availability**

583

584 Freyja is hosted publicly on github (<https://github.com/andersen-lab/Freyja>) and is available
585 under a BSD-2-Clause License. Freyja is accessible as a package via bioconda
586 (<https://bioconda.github.io/recipes/freyja/README.html>) in container form via dockerhub
587 (<https://hub.docker.com/r/andersenlabapps/freyja>). COVID-19 Viral Epidemiology Workflow
588 (C-VIEW) is available at <https://github.com/ucsd-ccbb/C-VIEW> as an open-source, end-to-end
589 workflow for viral epidemiology focused on SARS-CoV-2 lineage assignment and
590 phylogenetics.

591

592 **Data Availability**

593

594 Consensus sequences from clinical and wastewater surveillance are all available on GISAID.
595 Spike-in sequencing data is available via google cloud
596 (https://console.cloud.google.com/storage/browser/search-reference_data).

597

598 **Acknowledgements**

599

600 We thank Dr. Alexander T. Yu of the California Department of Public Health (CDPH) for his
601 valuable suggestions and comments on the manuscript; Laralyn Asato and the Microbiology Lab
602 at the SD Public Utilities Department for providing us with county wastewater samples.
603 We thank UC San Diego's Return to Learn (RTL) program for funding the campus-wide
604 wastewater surveillance efforts. We also thank the rest of the RTL leadership team and Bradley
605 Sollenberger of the Operational Strategic Initiatives (OSI) team for ensuring the smooth
606 functioning of the program. We also thank Jason Kayne, Rich Cota, Jesus Ortiz, and the
607 Facilities management team (FM) at UCSD, Joseph Mayer from the Center for Aerosol Impacts
608 on Chemistry of the Environment (CAICE) and Luke Arnold of the Campus Research Machine
609 Shop (CRMS) for assistance with the installation and operation of the autosamplers; Robbie
610 Jacobs, Shawn Knepple and their team at UCSD Logistics for assisting with our daily sampling
611 efforts; Christopher Longhurst and the UCSD Health Information Services team; Brett Pollak
612 and the UCSD Information Technology Services team for assisting with the daily notifications;
613 Office of Academic Affairs for contact tracing and targeted campus messaging assistance; Jana
614 Severson, Patrick Hochstein, Hemlata Jhaveri, the UCSD HDH team, and the UCSD
615 Environmental Health and Safety (EHS) personnel; Jack Gilbert and the Microbiome Sample
616 Processing Core at UCSD for access to qPCR equipment. We also thank the CDC SPHERES
617 consortium, SEARCH (San Diego Epidemiology and Research for COVID Health) Alliance and
618 members of the Andersen lab for discussion and help with logistics. We thank the healthcare
619 workers, frontline workers, and patients who made the collection of this SARS-CoV-2 dataset
620 possible and all those who made genomic data available for analysis via GISAID.

621

622 **Funding**

623 This work has been funded by CDC BAA contracts 75D30121P10258 (Helix) and
624 75D30120C09795 (G.W.Y., R.K., L.C.L., and K.G.A.), NIH NIAID 3U19AI135995-03S2
625 (K.G.A.), U19AI135995 (K.G.A.), U01AI151812 (K.G.A.), NIH NCATS UL1TR002550
626 (K.G.A.), the Conrad Prebys Foundation (K.G.A.), NIH 5T32AI007244-38 (J.I.L.), NIH Pioneer
627 Grant 1DP1AT010885 (R.K.), NSF RAPID 2029069 (R.K.), San Diego County Health and

628 Human Services Agency (R.F.M), NIH S100D026929 (K.J.). The findings and conclusions in
629 this report are those of the authors and do not necessarily represent the official position of the
630 Centers for Disease Control and Prevention. Use of trade names is for identification only and
631 does not imply endorsement by the Centers for Disease Control and Prevention.

632

633 **Ethics declarations**

634 The University of California San Diego Institutional Review Boards (IRB) provided human
635 subject protection oversight of the of the data obtained by the EXCITE lab for the campus
636 clinical samples (IRB approval # 210699). All necessary patient/participant consent has been
637 obtained and the appropriate institutional forms have been archived, and any sample identifiers
638 included were de-identified. The wastewater component of this project was discussed with our
639 Institutional Review Board, and was not deemed to be human subject research, as it did not
640 record personally identifiable information.

Extended Data Figure 1: Relationship between genome coverage and cycle threshold. 10X genome coverage remains high, even for Ct values of nearly 38. Points indicate median value in each bin, while error bars indicate the median absolute deviation.

Extended Data Figure 2: Lineage-specific prediction of variant abundance in spike-in validation samples. A. Schematic of “spike-in” sample design. B-F. Lineage specific prediction. Proportions of each lineage in the sample are shown as a pie chart marker (Grey = Lineage A, Orange = Alpha, Pink = Beta, Turquoise = Delta, and Purple = Gamma) with error bars indicating the standard deviation from the mean, across four replicates.

Extended Data Figure 3: The rise of the Delta variant during Summer 2021. A. Mean SARS-CoV-2 viral gene copies/L of raw sewage (blue) collected from the Point Loma Wastewater Treatment Plant and caseload (gray) reported by the county during the same period. SARS-CoV-2 concentrations were normalized by PMMoV (pepper mild mottle virus) concentration to adjust for load changes. B. Lineage distribution in UCSD campus wastewater. C. Monthly lineage averages for wastewater collected at Point Loma Wastewater Treatment Plant during the Delta surge (N= 5, 20, 25, 7)
